

< Hide

For example, whenever a person asks for a number, often they just want an estimate. If the value is in the millions, they do not need to know the precise number of hundreds and tens. Likewise, if the value is in the billions, they do not necessarily care about little things like millions.

The closeness of the representation r of a number n is defined by $\text{abs}(r - n)$.

The input consists of:

- one line with the positive integer n ($1 \leq n \leq 10^{18}$).

Output the closest number to n with exactly one significant (non-zero) figure. If there are two equally-close answers, print the larger one.
